11th Comparative Analysis of Enterprise Data & COST Conference  
(CAED 2012)

26–28 April 2012, Nuremberg, Germany

# Motivation and Preview of Findings

- ▶ Firm survival: key element of industrial evolution (Caves, 1998; Tybout, 2000)
- ▶ ‘Being innovative’: feature of superior firms but has risks (e.g., high sunk development costs)

>>> We study the relationship between product innovation and plant survival for Chilean plants between 1996 and 2003

>>> Focusing on how RISK mediates that relationship

- ▶ Main findings
  - Product innovation is beneficial for the survival of Chilean plants
  - But the effects are heterogeneous: only multi-product plants and plants engaging in ‘cautious’ innovation benefit

# Contributions

- ▶ We add to the literature on firm survival and firm characteristics (e.g., Disney, Haskel and Heden 2003; Esteve-Perez, Llopis and Llopis 2004; Manjon-Antolin and Arauzo-Carod, 2008) by:
  - Using a novel measure of product innovation that is objective, plant-level and time-varying
  - Capturing incremental new-to-the-plant innovations which can be crucial in an emerging economy context
  - Examining the role of risk as a determinant of innovation-survival link
  - Using a more rigorous identification of the effects that accounts for unobserved firm heterogeneity

# Data and Some Statistics

- ▶ Unique dataset on Chilean manufacturing plants and their products collected by the Chilean Statistical Institute for period 1996–2003 (ENIA)
  - Allows us to identify plants part of multi-plant firms
  - Combined with older versions of ENIA follows plants since 1979
- ▶ Product innovation: dummy = 1 for plant in year  $t$  selling a 7-digit ISIC product it never sold prior to  $t-1$
- ▶ Average share of plants introducing new products is 13.4%
  - Lowest for food, beverage, and tobacco industries
  - Highest for basic metals and wood industries
- ▶ Average yearly exit rate is above 9%
- ▶ 8% of plants are part of a multi-plant firm
- ▶ 51% of plants are multi-product

# Examples of 7-Digit ISIC Products

<b>4-digit-ISIC</b>	<b>Industry Description</b>	<b>7-digit ISIC</b>	<b>Product Description</b>
<b>3117</b>	<b>Manufacture of bakery products</b>	<b>3117101</b>	<b>Bread of any kind, size and quality (except for sweet bread)</b>
		<b>3117402</b>	<b>Mixed dough (for different types of cakes)</b>
		<b>3117201</b>	<b>Cookies, with and without sugar and filled</b>
		<b>3117301</b>	<b>Noodles, pasta including macaroni</b>
<b>3311</b>	<b>Sawmills, planing and other wood mills</b>	<b>3311997</b>	<b>Saw log and/or shaped log</b>
		<b>3311119</b>	<b>Log produced in all types</b>
		<b>3311302</b>	<b>Wooden boards for prefabricated houses</b>
		<b>3311306</b>	<b>Wooden doors with or without glass</b>

# Model Specification (1)

- ▶ ‘Hazard’ model to estimate probability that a plant exits at  $t$  conditional on having survived until  $t-1$
- ▶ Cox proportional hazard model
  - Baseline hazard depending only on time duration is multiplied by an exponential function of plant characteristics
  - Allows to estimate the effects of plant characteristics without making assumptions on distribution of baseline hazard function
  - Assumes that the impact of any characteristic on a plant’s survival probability is independent of plant age
    - *We will check the validity of this assumption*

# Model Specification (2)

Our benchmark empirical specification is a conditional hazard function:

$$\lambda_i^1(t) = \lambda_0(t) e^{(\beta Innovation_{it} + \gamma X_{it} + I_t + I_r + I_j)}$$

To explore differences across multi- and single-product plants our main empirical specification is another conditional hazard function:

$$\lambda_i^2(t) = \lambda_0(t) e^{(\beta^1 Innovation_{it} * Multi + \beta^2 Innovation_{it} * Single + \gamma X_{it} + I_t + I_r + I_j)}$$

Rich set of plant controls in X addresses possibility that unobservables determine product innovation and survival

# Defining cautious innovators

- ▶ Risk of introducing a new product higher if the product is of substantial importance for a plant's overall revenues
    - Cautious: introduce new products on a small scale
  - ▶ Risks of engaging in product innovation are higher if the plant introduces new products but stops manufacturing old products
    - Cautious: introduce new products but keep old products
  - ▶ A plant follows a more risky innovation strategy if it introduces new products in a completely new industry in which it has less technical and market knowledge
    - Cautious: introduce new products in a known industry
- 

# Risk and Innovation

	Cox Proportional Hazard Regression		
	(1)	(2)	(3)
Product Innovation Less than 50% Revenues	<b>-0.238***</b> (0.082)		
Product Innovation More than 50% Revenues	<b>0.020</b> (0.105)		
Product Innovation without Product Dropping		<b>-0.615***</b> (0.120)	
Product Innovation with Product Dropping		<b>0.134*</b> (0.078)	
Product Innovation in an Old 4-digit Industry			<b>-0.207**</b> (0.092)
Product Innovation in a New 4-digit Industry			<b>-0.098</b> (0.091)
Year Fixed Effects	Yes	Yes	Yes

Observations	<b>20497</b>	<b>20497</b>	<b>20497</b>

**Product innovation has a positive effect on plant survival only for cautious innovators**

# Conclusion

- ▶ Innovation is powerful for plant survival ...
- ▶ ... but only under certain circumstances:
  - + multi-product plants, risk-mitigating innovators
  - single-product plants and plants engaged in risky product innovations are at greater risk of exit than non-innovators
- ▶ Exit risks explain plants' under-investment in innovation (in addition to the traditional rationales of a lack of appropriation of all benefits)
- ▶ Policies to help plants reduce the risks of innovation while keeping the right incentives are appropriate
